Project Review Report

Team members:	1. Aadi Kulkarni 2. Minseo Park 3. Leo
Product Name:	SpinShelf
How Might We…	How might we help older adults living alone reach everyday objects without risking a fall?

Section 1:

Review the responses on "I like…" and summarize the key words and ideas. "Frequency" represents the number of responses on the same key words or ideas.

"I like…"	**Frequency**
1. Strong statistics and background research made the problem compelling and grounded in facts	11
2. Clear focus on older adults and a real, high-impact safety problem	11
3. The rotating-shelf concept and its features (press a button and it rotates to you, reach items in the back)	9
4. The idea overall, and its creativity or uniqueness	9
5. Professional, organized presentation, with a clear split of team roles	8
6. Ideation process: realizing the robotic arm's limits and pivoting to a simpler design	7
7. Concept sketches, storyboards and persona	4

Section 2:

Review the responses on "I wish…" and summarize the key words and ideas. "Frequency" represents the number of responses on the same key words or ideas.

"I wish…"	**Frequency**
1. More explanation of the mechanism and how it works (motor, rotation speed, how it safely holds objects)	9
2. More and better visuals: color, UI visuals, showing objects on the shelves	7
3. More creative, or clearly different from a lazy susan or existing spinning shelves	7

4. It solved the vertical reach problem: spinning sideways doesn't help with high shelves, and low placement still means bending	6
5. Size, space and installation: big footprint, fit with existing built-in cabinets, portability	6
6. Slides that are less text-heavy, with bigger, more readable font	4
7. More detailed, clearer storyboards and sketches	3
8. Designed more around how older adults actually want to use technology	3
9. Clearer prototype plan and what questions it answers	2
10. Extra features, like a way to quickly find a specific item	2
11. Trim the background (1) vs. go deeper on it (1); problem scope felt roundabout (1)	3

Section 3:

Review the responses on "Other Comments" and summarize the key words and ideas. "Frequency" represents the number of responses on the same key words or ideas.

"Other Comments"	**Frequency**
1. Opening, sketches, creative matrix and prototype plan were clear and well explained (instructors)	2
2. Delivery: more eye contact and energy, trim the background, slightly over time (instructors)	2
3. Showed composure when something went wrong mid-presentation (peer)	1
4.	
….	

Section 4:

Based on the above feedback, the following are the improvements agreed by the team. For each improvement, provide the rationale (i.e. explain the reason why for the change/improvement)

Improvements	**Rationale**
1. Put SpinShelf at waist/counter height so frequently used items move out of high cabinets and into the unit.	6 reviewers said a sideways-spinning shelf doesn't fix reaching up high, and a low placement still means bending down. At waist height the user does neither, and reaching up and bending down are the motions that lead to falls.

2. Add one labeled button per section that rotates that section to the front with a motor.	7 reviewers said it felt too close to a regular lazy susan. With a lazy susan you still spin it by hand and reach into the back. One button press brings the item to you with no reaching or searching.
3. Add safety features: slow rotation, auto-stop if something blocks it, and a weight limit per section.	9 reviewers asked how the mechanism works and safely holds objects. A few also questioned whether older adults would trust and want to use the tech. Safety features make it predictable and easier to trust.
4. Make it a compact freestanding unit instead of a built-in cabinet.	6 reviewers raised size, space and installation, including fitting into kitchens that already have built-in cabinets. A freestanding unit needs no remodeling and can go wherever the user needs it.
5. Clearly show the mechanism next time: a diagram of the motor, buttons and rotation.	The most common “I wish” (9) was more explanation of how it works.
6. Presentation: more visuals and color, less text, a shorter background, timed rehearsals, more eye contact and energy.	7 reviewers wanted better visuals and 4 said the slides were too text-heavy. Instructors said to trim the background, watch the time, and bring more energy.

Section 5:

The updated plan on the ***rapid and low fidelity prototype(s)***:

What do we need to communicate to our user?	SpinShelf is a freestanding cabinet at waist height. You press the labeled button for a section, and that section slowly rotates to the front, so you never reach up, bend down, or dig through the back of a cabinet.
What do we need to learn from our users?	1) Is it easier than how they get items now? 2) Would they trust a motorized cabinet and feel comfortable using it? 3) Are the buttons easy to see, read, and press? 4) Do the height and size work in their home? 5) Does the rotation speed feel safe? 6) What would they store in it?
How are we going to prototype this concept?	Look-like: a cardboard model at waist height showing

- look-like prototype? - function-like prototype?	the overall size, sections, and button layout. Function-like: a “Wizard of Oz” test. When the user presses a button, a teammate rotates the shelf by hand to imitate the motor. That lets us test the interaction and whether they trust it without building the servo system yet.
Rapid and low fidelity prototype(s): What are the materials used to make the prototype(s)? How to build the prototype(s) with the minimum effort, but still can help us to achieve the learning from the user during Nov 8-13?	Materials: cardboard or foam board, a lazy susan turntable, a box or small table as a stand to bring it to waist height, large printed paper buttons with section labels, tape or hot glue, and real household items to put on the shelves. Build:divide a cardboard cylinder into sections, mount it on the turntable, set it on the stand, attach a labeled button for each section, and fill it with everyday items. During the test, one teammate rotates it on cue while the others run the session and take notes. Takes a few hours.
